# A NEW APPROACH TO DEFORMING TRIANGULATED CATEGORIES

Alessandro Lehmann SISSA and University of Antwerp

### Motivation: the curvature problem

Let A be a dg-algebra over a field k. It is a well known problem in deformation theory [KL09] that (first order) deformations of A as a dg-algebra do not suffice to span its whole second Hochschild cohomology. It turns out [Low08; Leh24] that  $HH^2(A)$  parametrizes first order deformations of A as a *curved* dg algebra. This is a significant issue, since cdg algebras do not have classical derived categories [Pos10]; in particular, there is no obvious deformation of D(A) corresponding to a curved deformation of A [KLN10]. The same problem was observed by Lurie in a different setting: he essentially showed in [Lur11] that the functor

 $\operatorname{Def}_A \colon \operatorname{dgart}_k \to \operatorname{Set}$ 

which associates to a (dg) local artinian k-algebra R the set of R-deformations of A as a dg-algebra is not a (derived) deformation functor. The main question that we aim to answer is the following:

Which deformation of D(A) corresponds to a curved deformation of A?

Lurking behind this one is a more fundamental question: which notion of deformation of a triangulated category allows for the question above to have a positive answer? The usual one – which roughly corresponds to reducing the hom-sets of an opportune resolution – cannot work: to a curved deformation of A corresponds a curved deformation of the dg-category D(A), which does not have an underlying triangulated category. This question is a crucial step towards obtaining a satisfactory deformation theory for noncommutative schemes.

# cdg algebras

A cdg algebra A over a commutative ring R is a triple (A<sup>#</sup>, d<sub>A</sub>, c) where:
A<sup>#</sup> is a graded R-algebra;
d<sub>A</sub>: A<sup>#</sup> → A<sup>#</sup> is a degree 1 derivation;
c ∈ A<sup>#</sup> is a degree 2 element such that d<sub>A</sub>c = 0 and d<sup>2</sup><sub>A</sub> = [c, -].

A cdg module M over a cdg algebra  $\mathcal{A}$  is a pair  $(M^{\#}, d_M)$  where  $M^{\#}$  is a graded  $\mathcal{A}^{\#}$ -module and

 $d_M \colon M^{\#} \to M^{\#}$ is a degree 1 derivation such that  $d_M^2 m = cm$ .

Key point: if M and N are cdg  $\mathcal{A}$ -modules, then

 $Hom_{\mathcal{A}}(M, N)$ is a *complex*, so  $\mathcal{A}$ -Mod is a (pretriangulated) dg-category.

# The *n*-derived category

Let  $A_n$  be a cdg deformation of A over  $k[t]/(t^{n+1})$ . A cdg  $A_n$ -module M is n-acyclic if its associated graded with respect to the t-adic filtration is acyclic; this makes sense since each graded piece is a complex. The n-derived category  $D^n(A_n)$  is the Verdier quotient  $D^n(A_n) = H^0 A_n \operatorname{-Mod}/n \operatorname{-Ac}(A_n)$ .

### Theorem 1 ([LL24])

- The category  $D^n(A_n)$  is generated by n+1 explicit compact objects  $\Gamma_0, \ldots, \Gamma_n$ and the projection  $H^0A_n$ -Mod  $\to D^n(A_n)$  admits both adjoints;
- Calling  $A_i$  the induced deformation of order  $i \leq n$ , the restriction functor  $A_i$ -Mod  $\rightarrow A_n$ -Mod induces a system of fully faithful embeddings

 $D(A) = D^{0}(A_{0}) \stackrel{i_{1}}{\hookrightarrow} D^{1}(A_{1}) \hookrightarrow \ldots \hookrightarrow D^{n-1}(A_{n-1}) \stackrel{i_{n}}{\hookrightarrow} D^{n}(A_{n});$ 

• The abelian category  $Z^0A_n$ -Mod admits a model structure presenting  $D^n(A_n)$ ;

### The classical case

If  $A_n$  has no curvature, one can consider the classical derived category  $D(A_n)$ . One sees that there are strictly more *n*-acyclics than acyclics; it turns out that  $D^n(A_n)$  can be seen as a (partial) categorical resolution of  $D(A_n)$ . Indeed: • There is an embedding  $D(A_n) \hookrightarrow D^n(A_n)$ ;

# $D^n(A_n)$ as a categorical extension

The embedding  $D^{n-1}(A_{n-1}) \stackrel{i_n}{\hookrightarrow} D^n(A_n)$  admits both a left adjoint Ker  $t^n$  and a right adjoint Coker  $t^n$ . We also have the functor  $\operatorname{Im} t^n \colon D^n(A_n) \to D(A)$ . These functors do not need to be derived, since they preserve *n*-acyclics.

### Theorem 2 ([LL24])

However, cdg modules have no cohomology, so there is no obvious notion of a derived category of  $\mathcal{A}$  [Pos10; KLN10].

• The (dg) category  $D^n(A_n)$  is smooth if and only if D(A) is smooth.

induces an equivalence between the quotient  $D^n(A_n)/D^{n-1}(A_{n-1})$  and D(A).

Inductively, we see that  $D^n(A_n)$  is obtained by gluing n + 1 copies of D(A).

# **Deformations of triangulated categories (WIP)**

All triangulated categories and functors between them are appropriately enhanced. Let  $\mathcal{T}$  be a triangulated category. A first order predeformation of  $\mathcal{T}$  is the datum of a recollement

together with two natural transformations  $I \xrightarrow{\eta_1} K$  and  $Q \xrightarrow{\eta_2} I$ . The recollement data also induces a natural transformation  $K \xrightarrow{\alpha} Q$ ; a predeformation is said to be a deformation if  $\alpha$  induces a natural isomorphism  $\bar{\alpha}$ 

### Main result: a commutative diagram of deformations

Theorem 3 (WIP)

Let  $\mathcal{T}$  be a triangulated category. There is a bijection

 $\operatorname{Def}_{k[\varepsilon]}^{\operatorname{cat}}(\mathcal{T}) \xleftarrow{\kappa} \operatorname{HH}^{2}(\mathcal{T})$ 

between first order deformations of  $\mathcal{T}$  as a triangulated category and its second Hochschild cohomology.

The point of the bijection is that the gluing functor is the cone of the Hochschild cocycle.

Theorem 4 (WIP)

There is a commutative diagram of bijections

between the cone C of  $\eta_1$  and the cocone D of  $\eta_2$ . Denote with  $\operatorname{Def}_{k[\varepsilon]}^{\operatorname{cat}}(\mathcal{T})$  the set of first order deformation of  $\mathcal{T}$  up to equivalence.

Where  $\operatorname{cDef}_{k[\varepsilon]}^{\operatorname{Mor}}(A)$  is the set of curved deformations of A up to equivalence of 1-derived categories; the upper arrow was introduced in [Leh24], while  $\chi_A$  is the characteristic morphism introduced in [Low08].
